K.E photoelectron =
$$h\nu - \varphi$$

Stopping potential is to stop the fastest photoelectron

$$V_0 = hv - \varphi$$

so, K.Emax and Vo both increases.

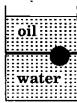

But K.E ranges from zero to K.E_{max} because of loss of energy due to subsequent collisions before getting ejected and not due to range of frequencies in the incident light.

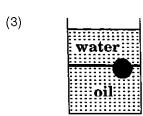

35. A ball is made of a material of density ρ where $\rho_{oil} < \rho < \rho_{water}$ with ρ_{oil} and ρ_{water} representing the densities of oil and water, respectively. The oil and water are immiscible. If the above ball is in equilibrium in a mixture of this oil and water, which of the following pictures represents its equilibrium position?

Sol.
$$\rho_{oil} < \rho < \rho_{water}$$

Oil is the least dense of them so it should settle at the top with water at the base. Now the ball is denser than oil but less denser than water. So, it will sink through oil but will not sink in water. So it will stay at the oil-water interface.
